Researcher Statement - Tier 1 Architectural Logic Failure

Supplemental Analysis of Issue 471526590 – Tier 1 Architectural Logic Failure
Statement: This report does not merely document a behavioral anomaly; it identifies a Cross-Environment Configuration Flaw resulting in systemic Resource Exhaustion ($O(n^2)$ Complexity) and State Persistence Failure (LLM-02/03).

During testing, I observed a mid-session 'Version Shift' (e.g., 2.5 to 3.0) which serves as an early warning sign for a Context Purge. This purge is an automated response to inefficient computational load, leading to 'Model Amnesia'—a critical vulnerability for institutional and high-stakes data integrity.

The Remediation: The solution provided—the 8/9 File System Stability Protocol—externalizes state persistence to bypass the internal 'Slow Burn' effect. This protocol has been successfully validated in-session to maintain logic integrity where standard architecture fails. I am requesting a Severity Upgrade to reflect the systemic fiscal bleed and the institutional risk associated with unmitigated state loss.
